

What are popular espresso cups like?

Measuring Popularity: In order to find what traits are associated with a successful product, we need a measure of success. The goal is to help inform a friend’s espresso cup business. However, the sales of a product is not displayed publicly on Amazon. To approximate a product’s sales, the number of reviews may be a good place to start. This is because only accounts that have purchased the product can review it. It is important to keep in mind that this metric of popularity is an approximation.

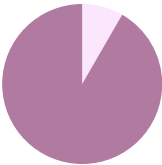

Select Review Rate Quantile

- ☐ Least Popular
- ☐ 6th quantile
- ☐ 5th quantile
- ☐ 4th quantile
- ☐ 3rd quantile

Material - Reviews per Week

To further investigate whether porcelain cups are more popular, I used multiple regression to control for related covariates:

Porcelain

Coefficient: 0.5594

Confidence Level: 95%

According to the model: On average, porcelain cups get 55% more reviews per day listed than non-porcelain ceramic cups.

Price-Review Rate

The relationship between the price and sales of products is crucial. Although this cannot help predict the outcome if we set our price at a given level, it does show that sellers trade off quantity of sales for price.

The regression coefficient indicates that for each 1% increase in the price of a cup, the number of reviews it gets per week fall by .64% on average

Listings with either saucers or multiple colors seem to be more popular. To further investigate whether these factors are related to popularity, I used a multiple OLS regression.

Includes Saucer

Coefficient: 0.5744

Confidence Level: 95%

Multiple Color Variants

Coefficient: 0.6341

Confidence Level: 95%

According to the model: On average, cups including saucers had 55% more reviews per week than those without. On average, Listings offering multiple color variants had 63% more reviews per week than those that didn't.

Differences in price~review rate relationship between materials

Differentiators: While it is important to know what attributes are popular among customers, it is also important to know whether customers are willing to pay more for attributes that are differentiators. The visualization on the left shows that the review rate of a ceramic cups are not as dependent on price as it is for porcelain cups. This suggests that customers may be willing to pay more for ceramic cups.

The hypotheses that the price-reviews relationship is different between products in the relevant categories was tested using multiple regression with interaction terms between the categories and price. Ultimately, there was insufficient evidence to conclude that any variable significantly changed customers's willingness to pay.
